

Customizing Your Elixir Website

A reference guide for making changes to elixir-portal — logo, text, photos, Instagram embeds, and general edits.

The Golden Rule for Every Change

No matter what you're changing, the workflow is always the same four steps:

- 1. Edit the file in VS Code
- 2. Save it (Ctrl+S)
- 3. In the terminal: `git add .`, then `git commit -m "describe your change"`, then `git push`
- 4. Vercel automatically rebuilds and redeploys within about a minute — refresh your live site to see it

You never need to touch Render or Supabase for visual/content changes — those only run your backend and database. Everything in this guide lives in the `frontend/` folder.

1. Changing the Logo and "Elixir" Wordmark

Right now your logo is a small heartbeat-line icon drawn directly in code (SVG), paired with the word "Elixir" in italic serif type. You can change either or both.

Option A — Replace the icon with your own image

frontend/public/logo.png

Drop your logo image file into the `frontend/public` folder (create the folder if it doesn't exist). Name it something simple like `logo.png`.

Then edit: `frontend/src/components/Navbar.jsx`

Find this block near the top of the file:

```
<svg width="30" height="30" viewBox="0 0 30 30" aria-hidden="true">
  <path d="M2 15 H10 L12 6 L16 24 L19 15 L22 15" ... />
</svg>
<span className="font-display italic text-2xl tracking-tight">Elixir</span>
```

Replace the whole block with:

```

<span className="font-display italic text-2xl tracking-tight">Elixir</span>
```

Because the file lives in `public/`, you reference it starting with a forward slash (`/logo.png`) — not the full folder path.

Option B — Change the wordmark text or font

To rename "Elixir" to something else, just edit the text between the `<span>` tags shown above. To change the typeface, open `frontend/index.html` and swap the Google Fonts link for a different font family, then update `frontend/tailwind.config.js` under `fontFamily.display` to match the new font's name.

Also update the Footer

`frontend/src/components/Footer.jsx`

The footer repeats the wordmark in a line like `<span className="font-display italic...">Elixir</span>` — apply the same change there for consistency.

2. Adding or Editing Text on a Page

Every page is a separate file. Find the one you want to change, then edit the text directly inside the JSX (the HTML-like code) — anything inside quotes or between tags is safe to rewrite.

Page	File
Home	frontend/src/pages/Home.jsx
Find Donors	frontend/src/pages/FindDonors.jsx
Blood Info	frontend/src/pages/BloodInfo.jsx
Helpline	frontend/src/pages/Helpline.jsx
Register as Donor	frontend/src/pages/RegisterDonor.jsx
Top navigation	frontend/src/components/Navbar.jsx
Bottom footer	frontend/src/components/Footer.jsx

Example: changing the homepage headline

frontend/src/pages/Home.jsx

Find this near the top:

```
<h1 className="text-4xl md:text-5xl leading-[1.1] font-semibold text-ink">
Somebody, somewhere, is waiting for your blood type right now.
</h1>
```

Just rewrite the sentence between the tags — formatting and layout won't change.

Example: adding a brand-new paragraph or section

To add a new line of text, add a new `<p>` tag near similar ones. For example, to add a sentence under the hero subheading in Home.jsx:

```
<p className="mt-6 text-ink/70 max-w-prose leading-relaxed">
Elixir connects verified donors with patients, hospitals and blood banks in
minutes, not hours. No paperwork, no waiting rooms – just people helping people.
</p>

<p className="mt-3 text-ink/70 max-w-prose leading-relaxed">
Your new sentence goes here.
</p>
```

The class names (things like `mt-3`, `text-ink/70`) control spacing and color — copy them from a nearby element so new text matches the site's style.

3. Adding Photos to a Page

Option A — Local images (recommended for logos, team photos, fixed content)

Put image files into `frontend/public/images/` (create this folder). Then reference them anywhere with an `<img>` tag:

```

```

Keep photos under ~500KB each where possible (use tinypng.com to compress) so the site stays fast to load.

Option B — Hosted images (good for photos you'll swap often)

Upload the photo to a free host like [Imgur](https://imgur.com) or [Cloudinary](https://cloudinary.com), copy the direct image URL, and use it the same way: `src="https://..."` instead of a local path. This way you can change the photo later without touching code — just re-upload with the same URL if your host supports it, or update the link in the file.

Example: adding a photo row to the Home page

```
<section className="max-w-6xl mx-auto px-6 py-16">  
  <h2 className="text-2xl font-semibold max-w-md">Moments from our donation  
  camps</h2>  
  <div className="mt-8 grid sm:grid-cols-2 lg:grid-cols-3 gap-6">  
      
      
      
  </div>  
</section>
```

Paste a block like this into any page file (e.g. `Home.jsx`), between two existing `<section>` blocks.

4. Showing Live Instagram Posts

There's no single "correct" way to do this — it depends on how much control and how much setup effort you want. Three realistic options, easiest first:

Option A — Embed individual posts (easiest, no account setup)

Instagram lets you embed any single public post for free, no login or API needed:

- Open the Instagram post in a browser, click the **⋮** menu, choose "Embed"
- Instagram gives you a small block of HTML code
- Paste it into any page file wrapped in a container

Downside: you have to manually re-embed a new post whenever you want to update it — it won't auto-update as you post more.

Option B — A live auto-updating feed widget (recommended)

Services like Elfsight, SnapWidget, or Behold let you connect your Instagram account once, then give you a small embed snippet that always shows your latest posts automatically. Most have a free tier for a small number of posts.

- Sign up at elfsight.com (or snapwidget.com) and connect your Instagram account
- Customize the feed's look (grid size, number of posts) in their dashboard
- Copy the embed code they generate

Then in your project:

frontend/src/pages/Home.jsx (or wherever you want it)

```
<section className="max-w-6xl mx-auto px-6 py-16">
  <h2 className="text-2xl font-semibold max-w-md">Follow us on Instagram</h2>
  <div className="mt-8">
    { /* Paste the embed code/script from Elfsight or SnapWidget here */ }
  </div>
</section>
```

If the embed code includes a `<script>` tag, you may need to add it to `frontend/index.html` instead (inside the `<head>`) rather than directly in a React component — the widget's own instructions will tell you which.

Option C — Instagram's official Graph API (most control, most setup)

This is the "do it yourself" route: create a Meta Developer app, connect a Business/Creator Instagram account, and fetch your own posts via API calls from your backend. It gives you full control over styling but requires Meta App review for production use and ongoing token refresh handling. Only worth it if the widget services above feel too limiting — for most portfolio/NGO sites, Option B is the practical choice.

5. Other Common Changes

Changing colors

frontend/tailwind.config.js

All site colors are defined once here as named tokens (wine, amber, teal, paper, ink). Change the hex values and the whole site updates everywhere that color is used:

```
colors: {
  wine: {
    DEFAULT: '#7A1B33', // main brand red – nav, buttons
    deep: '#4A0F1F', // hover state
  },
  amber: '#E3A23C', // call-to-action accent
  teal: '#2E6B5E', // secondary accent
  paper: '#F7F1E8', // background
}
```

Adding a brand-new page

Three steps:

- Create a new file, e.g. frontend/src/pages/About.jsx, following the shape of an existing page
- In frontend/src/App.jsx, add a new <Route path="/about" element=<About /> /> line
- In frontend/src/components/Navbar.jsx, add { to: '/about', label: 'About' } to the links array

Changing contact numbers / helpline info

These come from your Supabase helpline table, not the code. Open Supabase → Table Editor → helpline, and edit the rows directly. Changes appear on the live site immediately, no deploy needed.

Changing the footer credits / tagline

frontend/src/components/Footer.jsx

Edit the text directly — the tagline, the "Built by" names, and the copyright line are all plain text inside this file.

Tip: whenever you're not sure which file controls something you're looking at, right-click the text on the live site → Inspect, and look at the class names shown — search for that same class name across your project in VS Code (Ctrl+Shift+F) to jump straight to the right file.
